NEWSLETTER

NOVEMBER 1992

844 CHARLES STREET,

MOORPARK, CA. 93021

A.M.A. CHARTERED CLUB # 1943

EDITOR: BOB SWET

2600 PONDEROSA DRIVE, #15

CAMARILLO, CA. 93010

PRESIDENT:

Mike Leal 844 Charles Street Moorpark, CA 93021 (805) 529 - 7535

VICE PRESIDENT:

Thomas Akers 1583 Wakefield Ave. Thousand Oaks, CA 91360 (805) 496 - 6655

SECRETARY:

Larry Jimenez 1943 Channel Drive Ventura, CA 93001 (805) 652 - 1937

TREASURER:

Bob Swet 2600 Ponderosa Dr., #15 Camarillo, CA 93010 (805) 388 - 9619

CLUB WINCHES:

Thomas Akers (805) 496 - 6655 Mike Leal (805) 529 - 7535 Edgar Weisman (805) 496 - 0611

NEXT CLUB CONTEST:

Date Saturday, December 12
Place Paramount Ranch, Agoura
Time 9:00 a.m.
C/D Edgar Weisman

NEXT CLUB MEETING:

Date November 24, 1992
Day ** TUESDAY **
Place Cameron House
Time 7:30 p.m.

TOSS NOTES FOR OCTOBER MEETING

No OLD BUSINESS to discuss.

NEW BUSINESS:

- 1) Most of the meeting was devoted to the up coming SC² contest on November 22nd. And since we only had 9 members present the rest of the meeting was spent nominating officers for next year.
- 2) The NOMINEES for 1993 are:

PRESIDENT......MIKE REAGAN
VICE PRESIDENT......EDGAR WEISMAN
SECRETARY.....THOMAS AKERS
TREASURER.....MIKE LEAL
NEWSLETTER......MIKE LEARRY JIMENEZ

IF YOU WOULD LIKE TO NOMINATE SOMEONE ELSE PLEASE COME TO THE NOVEMBER 24TH MEETING! ***LARRY***

NOTES FROM YOUR EDITOR

Last month I wrote an article "Heavier Than Hot Air" in hopes to elicit some responses from all you members that we have not seen from in the past months. I have heard from only three people, so I guess that we won't be losing to many members during the 1993 membership sign-up currently in process. Here are the responses:

Jim Bennett is resigning to pursue his Power Plane flying. We certainly wish him the best of luck. Just remember Jim, when you tired of cleaning up that goo, there are those clean, quiet, relaxing sailplanes to be flownand may all your deadstick landings be with a sailplane.

John VanHamerveld is going to retire from sailplanes and pursue his activities in electric powered flight. During the past few months, John has hooked up with another R/C flier and has been enjoying his latest designs. For the past few years, John has been teaching courses in model airplane construction at the Thousand Oaks Civic Center and has been an instructor at all of the Delta Cub Contests. We certainly hope that you continue to do your fine work with the pilots of tomorrow. TOSS would like to thank you for all of your help in the past. Remember - keep those batteries charged, wings level and "watch the plane". Best of luck to you John.

P.S. Thank your wife for all the help that she too has given over the years.

One of the members commented on the fact that they live some distance away and should not be expected to show up at every activity. My response is that he is correct. We don't! The article was written for those "locals" who haven't shown up for any activities. If you do live far away, try car-pooling with another member. The roster is published so that you can contact other members for such purposes.

TOSS is committed to a couple of activites each year such as the SC² Contest and the Delta Cub Contests. All members should make attempts to assist in the operation of these functions. Without these contests, OUR club will be forced to increase dues and to seek a new flying sight. So come on out, it is for your own benefit.

DELTA CUB CONTEST

It was a great way to spend a morning. The weatherman allowed us perfect conditions for the event. The Park event fliers yielded the contestants, approximately 35 to 40 kids ranging in age from 7 to 14. Our donors provided us with Delta Cubs, building materials, and prizes. Speaking of prizes, we gave away four rubber band (stage two) kits, 7 gift certificates worth a total of \$50 dollars and a R/C BEDE-6 power plane kit. The DAILY NEWS provided us with media coverage (see the Sunday, Nov 15, Agoura edition).

Each time we do this event, it gets better and better. This was certainly the best one so far. We had just enough instructors/assistants to cover the group. Plane damage and roof landings were minimal. In general, fun was had by all.

Flyoffs were conducted in ten rounds with all contestants participating in each round until they had won two rounds. This gave everyone a good chance to win a prize. In the event of a tie, a flyoff was used to determine the winner. After the ten rounds, we had 8 winners and a flyoff was held among these contestants for the grand prize (the BEDE-6). Alot of kids went away happy and promising to return for the next event.

TOSS would like to thank all the hobby stores (MARTY'S, RADIOWAVE and the RED BARON) for their generous donations for without you, this event could not exist. I, on behalf of the rest of TOSS, would like to thank the NPS for allowing us to use Paramount Ranch to hold the contest. Lastly, we all should thank the members who made it happen.

-Bob Swet-

HOW TO TRIM YOUR SAILPLANE by Herb Stokely SBSS Silent Flyer Rewritten by Ron Kucera

I had a letter from a reader who questioned a statement that I made in a recent column. The note that he referred to mentioned that a nose heavy model will tend to porpoise and stall. I brought it up because it's not intuitive that it would work that way and newer fliers are likely to try to correct that condition by adding weight to the nose rather than removing it.

Longitudinal Stability

A plane uses dihedral in the wings to get lateral (or turning) stability. There is a dihedral effect for the longitudinal (diving/climbing) stability as well. This "longitudinal dihedral" comes from the relationship between the wing incidence, the horizontal stabilizer incidence, and the location of the center of gravity. Very simply, if the wing is set with its leading edge raised slightly, and the planes trims out in flight with the stab leading edge slightly lowered, you can visualize a kind of dihedral between the two surfaces that will stabilize the plane by making the nose come back up if the plane is tipped into a dive, thus longitudinal dihedral. It's not a correct technical term, but it does give the idea.

When the plane is too nose heavy, it takes a big, inefficient, down load on the tail to balance out the nose heaviness in trimmed flight. That equates to too much longitudinal dihedral, and the plane is too stable in pitch. All of that down load comes from a downward lift on the stabilizer that produces unnecessary drag, and subtracts from the lift of the wing so that it has to lift more to hold up the weight of the model and counter the down load on the tail. That's why most sailplanes fliers like to get the plane on the verge of tail-heaviness at

thermalling speeds. If the plane is balanced perfectly, there's sometimes almost no down load on the tail at all during slow speed flight. That means that the drag of the tail is at an absolute minimum, and the plane's aerodynamic efficiency benefits.

Balancing Isn't Always Easy

The problem of finding the best starting balance point for a new model is not always simple. Even kit planes or models built from plans don't always work well when balanced according to the directions. I've seen magazine plans that don't even show the balance point. Probably the construction article told in detail how to locate the C.G., so the author didn't bother to show it on the plans. Of course, when you later order the plans, the article probably doesn't come with them so you're on your own to find the right C.G. to start flying with. Likewise, if you're designing your own model, obviously you have to decide where to set up the initial balance point.

You can use one of the excellent computer programs available that propose a starting point, or you can use one of the textbook or graphic methods available, or you can even just use your own experience to estimate it intuitively. However you find that starting C.G. position, you will find that it has to be further refined in flight if you want to get it just right for your specific plane, your flying conditions, and for your flying style. Those first few hand launches can be scary, though, if you're not confident that the balance point is in a safe place. Try the free flight method. Make those first couple of hand launches over deep grass or weeds. Find something to cushion the landing enough to be

Fine Tuning - In Flight

Once the plane is safe to fly, here is how to get the C.G. in the right place for you. With smooth air

conditions, get the airplane trimmed for slow minimum sink flight. Fly it around a bit and tweak the elevator trim till you are sure that the plane is flying just about as you'd like for thermalling flight. Now use forward elevator to tip the plane into a shallow dive and ease the stick back to neutral. If the plane immediately pulls out of the dive and quickly zooms into a stall, it is nose heavy. That's right, the excess up (elevator trailing edge up) trim needed to hold up the excess nose weight becomes more powerful as speed builds up in a dive and lifts the nose further than it should for a smooth recovery, and the nose pitches up into a stall or porpoising maneuver.

If the plane continues to dive without pulling up, perhaps even steepening the dive - even though the stick has been brought back to what was neutral - the plane is tail heavy. In this case, the elevator trim needed for stable slow speed flight was too much down (elevator trailing edge down). The excess lift on the tail is needed to hold up or balance the tail heaviness. When the speed builds up in a dive, the lift on the tail becomes much stronger, and it causes the dive to continue steepening.

There are lots of other things happening besides just the speed build-up that affects what happens when you're dive-trimming a model. First, there is downwash on the tail caused by the lift on the wing. The wing makes lift by accelerating the air in a downward direction. The tail has to fly in this downflow behind the wing, and when the plane is flying at high lift (slow speed), the downwash is at its strongest and it helps hold the tail down (or the nose up, depending on how you think about it). When you put the plane into the dive, the downwash decreases, and some of the nose-up effect goes away. Also, the effective aerodynamic center (or neutral point) of the plane moves toward the rear, changing the stability characteristics of the plane.

THE EAGLES NEST - SACRAMENTO VAILEY SYRDYG SOCIETY

REPRINTED. FROM MRCSS 1/9

page

Flying Speed Is The Biggest Factor

All in all, though, the speed increase is the big effect. The lift on the tail (in an up or down direction) increases with the square of the speed, so a relatively small speed increase makes for a big change in the forces being produced by the tail. That means that trim on any reasonably normal plane will be dominated by the "longitudinal dihederal", or the slow speed trim position of the elevator.

Suppose that the planes porpoises when you try the dive trim maneuver. Since I said that means the plane is nose heavy, you should take some weight out of the nose, and retrim the elevator with a couple of hand tosses. When it seems to be trimmed right. launch again, fly around a bit to get the best thermalling trim, and try the divé maneuver again. This time it should pull out more gradually. The ideal balance is set when the pull out is smooth and gradual, and no stall occurs when the plane recovers; though all stable planes will go through some continuing oscillations.

Don't Push To Far

Try to be reasonable about this. Pushing the C.G. back is good - to a point! It unloads the horizontal tail during thermalling, and makes the plane more efficient aerodynamically. It also makes the model more responsive, or even touchy on the elevator control, and generally gives a feeling of lightness and better handling to the pilot. If however, you go a bit too far, bed things can happen when you retrim the plane for higher speed flying. Perhaps you are trying to penetrate on a windy day, or maybe you're working a cross country task where higher cruising speed is needed. Now your plane that pulled slowly out of the test dive on your earlier trim testing, becomes very touchy on the elevator, and may even want to tuck under or dive uncontrollably when you get it moving fairly fast.

What that means is that the "longitudinal dihederal* has become very small, and those other factors are taking over. Both of them tend to make the plane dive. The loss of downwash on the tail is the same as putting in just a bit of down elevator trim, and the aft movement of the neutral point makes the plane seem to be more nose heavy than it was. The result is that a plane that has its C.G. too far to the rear is very unpleasant to fly. So, test this too. After you get the plane balanced and flying just the way you like it at thermalling speed, feed in just enough down trim to pick up the speed to the point of good efficient penetration or cross country flight. Fly it around a bit to make sure you have it trimmed the way you want it and then do the dive trim maneuver again. It should still pull out smoothly, though perhaps a bit more slowly than before. If it wants to keep diving, or tries to tuck under, put back some of the weight in the nose. It's not worth it to have a plane that flies on the ragged edge of instability all of the time, even if there is a tiny theoretical performance advantage. To me, good handling is half of the enjoyment of the model, and bad flying planes are no fun!

Obviously, none of this will work if you have limp control rods, loose linkages, or poor servos that don't come to the same neutral every time. You can fly and enjoy models like this, but Fine Tuning is out of the question. For really precision flying, you need excellent equipment and a very precise, careful installation.

C.G. Effects On Tow Are Surprising Too

While I'm talking about locating the C.G. of a model, I might as well go on and mention that changing the C.G. location has an unexpected effect on the way a model behaves during a winch type launch. I've seen people try to improve the way a

plane acts on the winch by changing the C.G. and the effect here is intuitively backwards too.

What happens on tow during a winch launch is that as line is taken in, it accelerates the plane towards the turn-

around pulley on the other end of the field. The plane meanwhile is trying to climb on a circular path with the turnaround pulley near its center, so there is a big angle between the fuselage and the tow line during most of the launch. As the towline pulls the plane toward the turnaround, the heavier parts of the plane tend to stay on the path that they are following and the lighter parts tend more to be pulled in the direction of the line. If you can visualize that action, on an extremely nose heavy model, you can see that the nose will tend to stay on its upward path, while the lighter tail will be pulled toward the turnaround. That gives a strong nose-up movement, as far as the flight path is concerned, and the plane will tend to stall. A tail heavy plane obviously will behave just the opposite, tending to drop its nose as the winch line pulls in.

Move The Tow Hook

Trim the plane for flight first, and then fix the launch problems by moving the hook. It's the only way. Start with the hook a bit forward, and slowly move it to the rear on successive launches, until you get maximum height and a good straight tow with no elevator input. Hauling back on the elevator during the launch should cause a properly set-up model to stall. If it doesn't, move the towhook back until it does, and then leave the elevator alone during launch. Actually, maximum launch height comes from having the hook so far back that you need down elevator trim on tow, but if you get distracted, and forget to retrim before launch. the plane will stall and you might not catch it in time.
